```
ARM-Average Run equivalent Method
    by Clem Comly June 20, 2000
```

I would like to present my findings on a method to analyze more completely the ability of outfielders to shut down the running game. In the past OF assists and anecdotal evidence were used. More recently, the STATS Scoreboard has presented the percentage of runners who have taken the extra base when the opportunity was provided. Let's call this new method ARM (Average Run equivalent Method). ARM takes into account assists, extra bases taken by either the batter or the runner, and errors made by the outfielder whenever a single is fielded with runners on first and/or second (regardless of the third base runner situation). ARM, which requires play-by-play data was used for most of the major league games from 1959 to 1987 (thanks to Retrosheet and the Baseball Workshop). Data for different OF positions are kept separate. Among other questions ARM could let us answer is what is the difference between having Greg Luzinski in LF rather than Carl Yastrzemski for a full season (and the answer is not 43 pounds despite what TB says).

First, we use play-by-play (p-b-p) to identify situations where we know a single was hit to a specific outfielder. ARM notes his name, the outs and the runner positions before the hit, and the result. If there was no runner on first nor on second, ARM discards the result. If there is a runner on 3B also, 99\% of the time we throw that runner away but keep the result of the other runners. The less than $1 \%$ of the time where the OF throws out the runner from 3B at home, ARM treats as if the runner on 3B had been on second. Any subsequent infielder error or pickoff of a runner is not recorded as the actual result, but instead a best guess of the result without that extraneous play. The OF gets no credit for the out on the bases unless he gets an assist, but he does get credit for an out when he gets an assist but the runner was actually safe when an infielder dropped the throw for an error.

So in effect there are 9 starting states: 3 out possibilities multiplied by three runner situations: man on first ( 100 below), man on second (020), and men on first and second (120). For each event from the p-b-p, ARM records the resulting runner positions, any out that was made by the OF's throw (+ below), and any runs scoring (- is 1 run, = is two runs). When ARM has finished for a particular OF for a particular position, ARM uses Pete Palmer's expected runs (see The Hidden Game of Baseball, p.153) for the resulting out and base situation and adds 1 for each run scored. This sum is multiplied by the number of times that result was achieved on a single to that OF and all of these sums are added together and then ARM subtracts the product of the average expected runs for each state for that OF position and the number of times the OF handled a single in each initial state.

In the period 1959-1987, for instance, two center fielders with similar raw numbers are shown below:

| Name | S | MS | S w/ <br> $1 / 2 / 12$ | Assists on <br> $1 / 2 / 12$ |
| :--- | ---: | ---: | ---: | :---: |
| Rick Miller |  | 1313 | 116 | 539 |

To interpret the headings, in that period the p-b-p showed 1313 singles hit to CF while Miller was playing there. Some singles in the p-b-p are anonymous in terms of who fielded them. While Miller was in CF, there were 116 that on a pro rata basis were hit to him which I will call MS (missing singles). These 116 are strictly to show the level of accuracy of the p-b-p and are not included in the 1313. ARM looked at the 539 singles of the 1313 that happened with runners on first and/or second regardless of the runner on 3B. Miller garnered 16 assists after fielding those 539 singles. Looking at Cardenal, his assist total is significantly higher while the singles are a little higher. Calculating the ARM for Miller on those 539 hits, he saved his team 9 runs for his career from 1959-1987 compared to the baseline CF. This can be broken down into the three base runner starting positions which, allowing for rounding, add up to that -9.0.

\[

\]

Cardenal is worse, for the most part, due to his performance with a runner on first without a runner on second. What was the problem? Let's add together the 0 out, 1 out, and 2 out events and compare them to get an idea.

CF man on first not on second (symbolized as 100, where 123 is bases loaded, 103 is first and third occupied, etc.), SUM* of 0 outs, 1 out, and 2 outs

## Result situations

| Name | Opp | $100+$ | $020+$ | $003+$ | 120 | 103 | 023 | $100-$ | $020-$ | $003-$ |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| Rick Miller | 292 | 3 | 0 | 1 | 194 | 81 | 4 | 0 | 8 | 1 |
| Jose Cardenal 288 | 5 | 1 | 3 | 127 | 126 | 16 | 5 | 4 | 1 |  |

*NOTE: ARM calculates for each out situation separately. The summarization is simply to make it easier for the reader to evaluate the data.

As an example, the ending expected run values for a starting case of 1 out and one runner on (beginning runner position is irrelevant) are:

$$
\begin{array}{llllllll}
100+020+ & 003+ & 120 & 103 & 023 & 100- & 020- & 003- \\
.209 .348 & .382 & .888 & 1.088 & 1.371 & 1.478 & 1.699 & 1.897
\end{array}
$$

The baseline CF result average is 0.975 for the starting situation of one out and a runner on first. Cardenal threw out more runners $(9(5+1+3)$ to $4(3+0+1))$ and was only slightly worse in allowing the runner to score from first $(10(5+4+1)$ to $9(0+8+1)$. Cardenal's problem was the runner was going to third almost half the time (49\%, (126+16)/288) while Miller was at $30 \%$ $((81+4) / 292)$. ARM balances these factors and shows Miller is more valuable.

Let's look at a gold glove versus a hitter, Yaz versus Luzinski. Key:
GS Games Started in LF
S singles fielded
MS prorated unidentified singles
TS singles fielded with a runner on 1B and/or 2B regardless of 3B (excluding MS) ARM equivalent runs minus base line LF
A assists on singles fielded with man on 1B and/or 2B regardless of 3B
Yastrzemski

| Season | GS | S | MS | TS | ARM | A |  |  |

## CONCLUSIONS

The key point of this study is we now have an idea of how much this talent is worth. The difference from absolute best season to worst is about 2 victories (around 20 runs). This is a combination of:

- the limited number of opportunities in a season (usually 50-100 singles with a runner on 1B and/or 2B),
- the talent is one of degree not kind (everybody makes an error now and then and throws out a runner now and then) to season, even the best don't average saving their teams 1 victory compared to an rom season average OF. Of course, the average RF in 1964 was 10\% Callison and $10 \%$ Clemente. Speaking of Clemente, a Pirate pitcher was quoted on SABR-L that Clemente liked to show off his arm by throwing to third base where there wasn't a play and let the batter get to second hurting the Pirates. Clemente's ARM reflects batters taking second, so overall he didn't hurt the Pirates (as his Gold Gloves also attest to), and
- the refusal of managers to keep putting a real rag arm in the field.

From season to season, even the best don't average saving their teams 1 victory compared to an average OF. Of course, the average RF in 1964 was $10 \%$ Callison and $10 \%$ Clemente. Speaking of Clemente, a Pirate pitcher was quoted on SABR-L that Clemente liked to show off his arm by throwing to third base where there wasn't a play and let the batter get to second hurting the Pirates. Clemente’s ARM reflects batters taking second, so overall he didn't hurt the Pirates (as his Gold Gloves also attest to). As Retrosheet holdings expand towards the present and further into the past, ARM can be calculated for more outfielders in baseball history. This methodology can be used for other studies. The one that springs to mind is base runner evaluation. Obviously, the average result of a single to LF with a runner on 1B is the result for the average left fielder is in large part the result of the average runner on 1B.

DISCLAIMERS (type enlarged by a factor of 10 for reader's benefit)
I purposely chose singles only because extra base hits are much more a function of the ball park. Also, the sample size is low for singles, for doubles and triples... ARM is limited to the accuracy of the p-b-p which no CPA would sign. More than $95 \%$, but not $100 \%$, of the games were available for the period 1959-1987. There may also be a slight bias that anonymous singles will tend to be hits on which no assist or error occurred. The baseline RF, CF, and LF were the averages of 3 ML seasons, 1961, 1966, 1968, and the NL of 1962 and 1969 which were chosen because of availability at the beginning of the project. For most seasons, the sum of all outfielders is a little better (below) than zero. If that bothers you, consider the baseline a replacement level player. I call this ARM, but it also measures the judgment of the OF and his ability to get into position to throw. Obviously, there may have been some singles that Yaz left his feet on that Luzinski let get by him for extra bases. ARM punishes Yaz for letting the runner go to third on those singles. Defensive average or range factor, which ARM supplements and does not replace, should reward Yaz for that play.
